How to Use Preparative HPLC - Part 2 Scaling up from Analytical HPLC

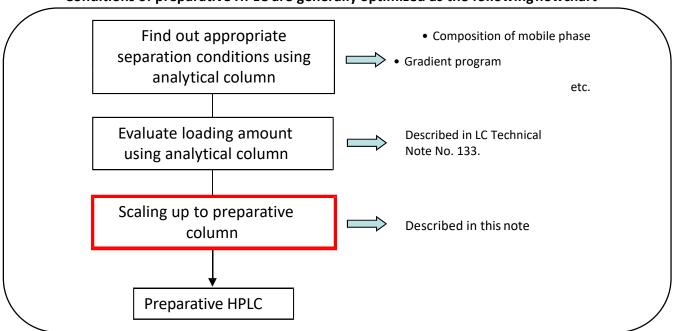

GL Sciences Inc.

It is not easy to find out optimal condition for preparative HPLC. Not only large volume of solvent but also substantial amount of precious sample may be required for the evaluation of separation conditions, particularly in preparative HPLC. Consequently, we recommend that the evaluation should be carried out using analytical column (4.6 mm I.D.) in the beginning. Condition for preparative HPLC can be investigated efficiently by using analytical column packed with the same gel as in preparative HPLC column.

In this note, Inertsil ODS-3 was taken as an example, and how to scaling up from analytical column to preparative column is described.

(K. Kanno)

$\label{lem:conditions} \textbf{Conditions of preparative HPLC are generally optimized as the following flow chart}$

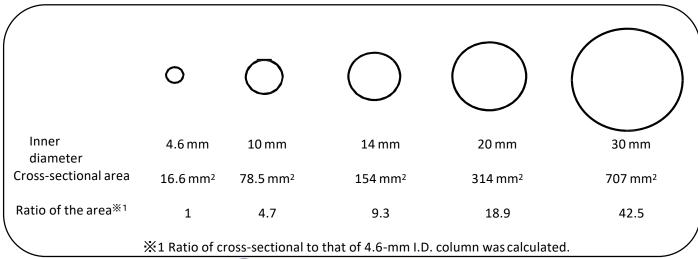

<What is important to scale up>

It is important to calculate ratio of cross-sectional area of preparative column to that of analytical column. The ratio can be used as follows;

1)Increase flow rate in proportion to cross-sectional area of column

2)Increase loading amount (injection volume) in proportion to cross-sectional area of column

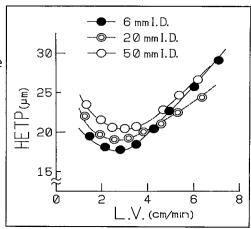

1) Increase flow rate in proportion to cross-sectional area of column

The figure shown right indicates relation between linear velocity of mobile phase and height equivalent to theoretical plate (HETP) obtained with three columns packed with 10 μ m particles.

Optimum flow rate, at which the lowest HETP is obtained, is 3.0 cm/min (0.5 mm/sec) for all the columns. Therefore, it can be said that flow rate should be changed to maintain optimum linear velocity of 3.0 cm/min in case of scaling up from 10 μm particle packed analytical column to 10 μm particle packed reparative one. It is important that particle size of the two columns is same because optimum flow rate changes also depending on particle size.

2) Increase loading amount (injection volume) in proportion to cross-sectional area of column

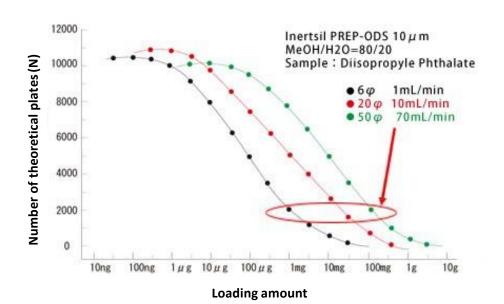

The figure shown below indicates relation between loading amount and number of theoretical plates (N). Three columns with different inner diameters were used and compared. For example, maximum loading amount for each column at which N above 2000 can be obtained is follows;

6 mm I.D. approx. 1 mg

20 mm I.D. approx. 10 mg

50 mm I.D. approx. 70 mg

Since the maximum loading amount is proportional to cross-sectional area of column, it can be said that similar separation should be achieved with preparative column as with analytical column by increasing injection volume in proportion to cross-sectional area.

GL Sciences LC Technical Note

< Parameters to be changed for scaling up >

In case of scaling up from a 4.6 mm I.D. analytical column to a 20 mm I.D. preparative column, cross-sectional area of the column is approximately 19 times enlarged. Therefore, scaling up can be achieved by increasing flow rate and loading amount (injection volume) 19 times. Red letters represent parameters to be changed for scaling up.

Scale up

Increase flow rate and

Keep other parameters

unchanged

injection volume 19 times.

Column : Inertsil ODS-3

(10 μ m, 4.6 mm I.D. \times

250 mm)

Eluent : A) CH₃CN B) H₂O

A/B = 40/60, v/v

Flow rate : $500 \,\mu\text{L/min}$

Column Temp. : 40 °C

Detection : UV 270 nm

Injection Vol.* : 500 µL

Column : Inertsil ODS-3

(10 μ m, 20 mm I.D. \times

250 mm)

Eluent : A) CH₃CN B) H₂O

A/B = 40/60, v/v

Flow rate : 9.5 mL/min

(9500 μL/min)

Column Temp. : 40 °C

Detection : UV 270 nm

Injection Vol.* : 9.5 mL (9500 山)

* Concentration of the sample solution is same
